(54) Abstract Title

Protected storage of core data secrets

(57) The invention provides central storage for core data secrets, referred to as data items. The architecture includes a storage server (104), a plurality of installable storage providers (106), and one or more authentication providers (108). Programming interfaces are exposed so that application programs (102) can utilize the services provided by the invention without having to actually implement the features. When storing a data item using the protected storage services, an application program can specify rules that determine when to allow access to the data item. Access can, if desired, be limited to the current computer user. Access can similarly be limited to specified application programs or to certain classes of application programs. The storage server authenticates requesting application programs before returning data to them. A default authentication provider authenticates users based on their computer or network logon. A default storage provider allows storage of data items on magnetic media such as a hard disk or a floppy disk. Data items are encrypted before they are stored. The encryption optionally uses a key that is derived from the previous authentication of the user. Specifically, the key is derived from the user's password, supplied during logon. In addition, an application program or the user can specify that certain items require another password that is entered whenever access to the data is requested. The default storage provider implements a multi-level encryption scheme to minimize the amount of encryption that has to be re-done when the user changes a password. Each data item is encrypted using an item key that is generated randomly by the system. The item key is in turn encrypted with a master key that is itself encrypted with a key derived from the user-supplied password (such as the user's logon password).

PROTECTED STORAGE OF CORE DATA SECRETS

TECHNICAL FIELD

This invention relates to systems and methods that provide central services for securely storing core data secrets such as passwords, cryptographic keys, and sensitive personal or financial codes.

BACKGROUND OF THE INVENTION

Increasingly, financial and other sensitive transactions are being performed by personal computers. This has increased the need for secure storage of data. Modern cryptography techniques are often used to protect such data from unauthorized access.

New security methods, however, have brought about a need to store and protect "core" data secrets, such as private cryptographic keys, credit card numbers, and other small pieces of secret data. Presently, this responsibility is left to individual application programs or to personal computer users themselves. Although programs are available that allow users to encrypt and store data, such programs cannot typically be used by other application programs. Currently, each application program has to devise a safe and secure method to store such data.

As an example of the problems associated with the current state of the art, consider the issues involved in exploiting smart card technologies. A smart card is particularly well suited as a receptacle for core data secrets such as those described above. In addition, smart cards can be used to authenticate users by requiring each user to insert his or her personal smart card into a receptacle associated with the user's personal computer. Tamper-proof smart cards have been designed for just these purposes.

1 Problems arise without agreed upon standards for using such devices.
2 Although a developer could provide capabilities for working with a limited
3 number of smart cards, it would be difficult or impossible to anticipate all the
4 different variations that might eventually arise. This fact makes it impractical to
5 implement smart card technology in various different applications.

6 Although some storage media such as magnetic hard disks do not present
7 the challenges of smart cards, many software developers simply do not have the
8 background and knowledge required to safely implement modern cryptographic
9 techniques. Even if they did, it would be inefficient for each developer to
10 undertake the complex task of developing a method of storing core secrets.
11 Furthermore, resulting solutions would be incompatible. It would be much more
12 preferable to adopt a common scheme for storing such data, and to avoid having to
13 implement a new solution for every different application program.

14 15 SUMMARY OF THE INVENTION

16 The invention described below provides central protected storage services
17 that can be called by application programs to store core secrets. An embodiment
18 of the invention is implemented as a server process and associated interfaces that
19 can be invoked by application programs to store and retrieve small data items.

20 The general method and architecture includes a storage server and a
21 plurality of installable storage providers and authentication providers. Each
22 storage provider is adapted to securely store data using a specific type of media,
23 such as magnetic media or smart cards. Details of the storage medium are hidden
24 from the calling application programs. Authentication providers are used to
25 authenticate users by different methods, such as by requesting passwords, by

1 reading smart cards, by retinal scans, or by other ways that might be devised in the
2 future. Again, authentication details are generally hidden from the calling
3 application programs.

4 Application programs interact with the storage server through well-defined
5 interfaces. A data item can be stored with a simple call to the storage server, and
6 can be retrieved later with a similar call. All encryption, decryption, item integrity
7 checks, and user authentication are performed by the storage server and its
8 associated providers. Because of this, application programs can take advantage of
9 advanced security features without adding complexity to the application programs
10 themselves.

11 When storing a data item using the protected storage services, an
12 application program can specify rules that determine when to allow access to the
13 data item. Access is generally limited to the computer user that created the data
14 item. Access can similarly be limited to specified application programs or to
15 certain classes of application programs. The storage server authenticates
16 requesting application programs before returning data to them.

17 A default authentication provider authenticates users based on their
18 computer or network logon. Other authentication providers can also be installed.

19 A default storage provider allows storage of data items on magnetic media
20 such as a hard disk or a floppy disk. Data items are encrypted before they are
21 stored. The encryption uses a key that is derived from the authentication of the
22 user. Specifically, the key is derived from the user's password, supplied during
23 computer or network logon. In addition, an application program or the user can
24 specify that certain items require an additional password to be entered whenever
25 access to the data is requested.

1 The default storage provider implements a multi-level key encryption
2 scheme to minimize the amount of encryption that has to be re-done when the user
3 changes a password. Each data item is encrypted using an item key that is
4 generated randomly by the system. The item key is in turn encrypted with a
5 master key that is itself encrypted (as described below) with a key derived from
6 the user-supplied password (such as the user's logon password).

7 8 **BRIEF DESCRIPTION OF THE DRAWINGS**

9 Fig. 1 is a block diagram of an exemplary computer system suitable for use
10 in implementing the invention.

11 Fig. 2 is a block diagram of a protected storage system and a calling
12 application program in accordance with the invention.

13 Fig. 3 is a process diagram illustrating how data items are encrypted and
14 authenticated in accordance with the invention.

15 16 **DETAILED DESCRIPTION**

17 **Cryptography Overview**

18 In general, cryptography is the process for encrypting or scrambling
19 messages such that the messages can be stored and transmitted securely.
20 Cryptography can be used to achieve secure communications, even when the
21 transmission media (for example, the Internet) is untrustworthy. Computer users
22 also use cryptography to encrypt sensitive files, so that an intruder cannot
23 understand them. Cryptography can be used to ensure data integrity as well as to
24 maintain secrecy. It is also possible to verify the origin of data items using
25 cryptography, though the use of using digital signatures. When using

1 cryptographic methods, only the cryptographic keys must remain secret. The
2 algorithms, the key sizes, and file formats can be made public without
3 compromising security.

4 Using data encryption, a data item can be scrambled so that it appears like
5 random gibberish and is very difficult to transform back to the original data
6 without a secret key. This message can consist of ASCII text, a database file, or
7 any other data.

8 Once a data item has been encrypted, it can be stored on non-secure media
9 or transmitted over a non-secure network, and still remain secret. Later, the
10 message can be decrypted into its original form.

11 When a data item is encrypted, an *encryption key* is used. This is
12 comparable to a key that is used to lock a padlock. To decrypt the message, a
13 *decryption key* must be used. The encryption and decryption keys are often, but
14 not always, the same key.

15 There are two main classes of encryption algorithms: *symmetric algorithms*
16 and *public-key algorithms* (also known as *asymmetric algorithms*). Systems that
17 use symmetric algorithms are sometimes referred to as *conventional*.

18 Symmetric algorithms are the most common type of encryption algorithm.
19 They are known as symmetric because the same key is used for both encryption
20 and decryption. Unlike the keys used with public-key algorithms, symmetric keys
21 are frequently changed.

22 Compared to public-key algorithms, symmetric algorithms are very fast
23 and, thus, are preferred when encrypting large amounts of data. Some of the more
24 common symmetric algorithms are RC2, RC4, and the Data Encryption Standard
25 (DES).

1 Public-key (asymmetric) algorithms use two different keys: the *public key*
2 and the *private key*. The private key is kept private to the owner of the key pair,
3 and the public key can be distributed to anyone who requests it (often by means of
4 a certificate). If one key is used to encrypt a message, then the other key is
5 required to decrypt the message.

6 Public-key algorithms are very slow—on the order of 1,000 times slower
7 than symmetric algorithms. Consequently, they are typically used only to encrypt
8 session keys. They are also used to digitally sign messages.

9 One of the most common public-key algorithms is the RSA Public-Key
10 Cipher.

11 Digital signatures can be used to distribute an unencrypted data item, while
12 allowing the recipients to be able to verify that the message comes from its
13 purported sender and that it has not been tampered with. Signing a message does
14 not alter the message, it simply generates a digital signature string that can either
15 be bundled with the message or transmitted separately.

16 Digital signatures are generated by using public-key signature algorithms: a
17 private key is used to generate the signature, and the corresponding public key is
18 used to validate the signature.

19 Authentication involves the process of verifying the identity of a person or
20 entity. Certificates are a common way to achieve authentication. A certificate is a
21 set of data that completely identifies an entity, and is issued by a *Certification*
22 *Authority* (CA) only after that Authority has verified that the entity is who it says
23 it is. The data set includes the entity's public cryptographic key. When the sender
24 of a message *signs* data with its private key (and sends a copy of its certificate
25 with the message), the recipient of the message can use the sender's public key

1 (retrieved from the certificate) to verify that the sender is who it says it is.
2 Certificates can also be used to verify that data (including application programs)
3 have been vouched for by a trusted source.

4 On a network, there is often a trusted application running on a secure
5 computer that is known as the Certification Authority. This application knows the
6 public key of each user. Certification Authorities dispense messages known as
7 certificates, each of which contains the public key of one of its client users. Each
8 certificate is signed with the private key of the Certification Authority.

9 The invention described below utilizes techniques such as the well-known
10 digital encryption, signing, and authentication techniques described above. For
11 further information regarding such techniques, refer to Schneier, Bruce; *Applied*
12 *Cryptography Second Edition: Protocols, Algorithms, and Source Code in C*; John
13 Wiley & Sons, 1996, which is hereby incorporated by reference. The following
14 discussion assumes general familiarity with these topics.

15 Exemplary Operating Environment

16 Fig. 1 and the following discussion are intended to provide a brief, general
17 description of a suitable computing environment in which the invention may be
18 implemented. Although not required, the invention will be described in the
19 general context of computer-executable instructions, such as program modules,
20 being executed by a personal computer. Generally, program modules include
21 routines, programs, objects, components, data structures, etc. that perform
22 particular tasks or implement particular abstract data types. Moreover, those
23 skilled in the art will appreciate that the invention may be practiced with other
24 computer system configurations, including hand-held devices, multiprocessor
25 systems, microprocessor-based or programmable consumer electronics, network

1 PCs, minicomputers, mainframe computers, and the like. The invention may also
2 be practiced in distributed computer environments where tasks are performed by
3 remote processing devices that are linked through a communications network. In
4 a distributed computer environment, program modules may be located in both
5 local and remote memory storage devices.

6 With reference to Fig. 1, an exemplary system for implementing the
7 invention includes a general purpose computing device in the form of a
8 conventional personal computer 20, including a processing unit 21, a system
9 memory 22, and a system bus 23 that couples various system components
10 including the system memory to the processing unit 21. The system bus 23 may
11 be any of several types of bus structures including a memory bus or memory
12 controller, a peripheral bus, and a local bus using any of a variety of bus
13 architectures. The system memory includes read only memory (ROM) 24 and
14 random access memory (RAM) 25. A basic input/output system 26 (BIOS),
15 containing the basic routines that help to transfer information between elements
16 within personal computer 20, such as during start-up, is stored in ROM 24. The
17 personal computer 20 further includes a hard disk drive 27 for reading from and
18 writing to a hard disk, not shown, a magnetic disk drive 28 for reading from or
19 writing to a removable magnetic disk 29, and an optical disk drive 30 for reading
20 from or writing to a removable optical disk 31 such as a CD ROM or other optical
21 media. The hard disk drive 27, magnetic disk drive 28, and optical disk drive 30
22 are connected to the system bus 23 by a hard disk drive interface 32, a magnetic
23 disk drive interface 33, and an optical drive interface 34, respectively. The drives
24 and their associated computer-readable media provide nonvolatile storage of
25 computer readable instructions, data structures, program modules and other data

1 for the personal computer 20. Although the exemplary environment described
2 herein employs a hard disk, a removable magnetic disk 29 and a removable optical
3 disk 31, it should be appreciated by those skilled in the art that other types of
4 computer readable media which can store data that is accessible by a computer,
5 such as magnetic cassettes, flash memory cards, digital video disks, Bernoulli
6 cartridges, random access memories (RAMs) read only memories (ROM), and the
7 like, may also be used in the exemplary operating environment.

8 A number of program modules may be stored on the hard disk, magnetic
9 disk 29 optical disk 31, ROM 24, or RAM 25, including an operating system 35,
10 one or more application programs 36, other program modules 37, and program
11 data 38. A user may enter commands and information into the personal computer
12 20 through input devices such as keyboard 40 and pointing device 42. Other input
13 devices (not shown) may include a microphone, joystick, game pad, satellite dish,
14 scanner, or the like. These and other input devices are often connected to the
15 processing unit 21 through a serial port interface 46 that is coupled to the system
16 bus, but may be connected by other interfaces, such as a parallel port, game port,
17 or a universal serial bus (USB). A monitor 47 or other type of display device is
18 also connected to the system bus 23 via an interface, such as a video adapter 48.
19 In addition to the monitor, personal computers typically include other peripheral
20 output devices (not shown) such as speakers and printers.

21 The personal computer 20 may operate in a networked environment using
22 logical connections to one or more remote computers, such as a remote computer
23 49. The remote computer 49 may be another personal computer, a server, a router,
24 a network PC, a peer device or other common network node, and typically
25 includes many or all of the elements described above relative to the personal

1 computer 20, although only a memory storage device 50 has been illustrated in
2 Fig. 1. The logical connections depicted in Fig. 1 include a local area network
3 (LAN) 51 and a wide area network (WAN) 52. Such networking environments are
4 commonplace in offices, enterprise-wide computer networks, intranets, and the
5 Internet.

6 When used in a LAN networking environment, the personal computer 20 is
7 connected to the local network 51 through a network interface or adapter 53.
8 When used in a WAN networking environment, the personal computer 20 typically
9 includes a modem 54 or other means for establishing communications over the
10 wide area network 52, such as the Internet. The modem 54, which may be internal
11 or external, is connected to the system bus 23 via the serial port interface 46. In a
12 networked environment, program modules depicted relative to the personal
13 computer 20, or portions thereof, may be stored in the remote memory storage
14 device. It will be appreciated that the network connections shown are exemplary
15 and other means of establishing a communications link between the computers
16 may be used.

17 The illustrated computer uses an operating system such as the Windows
18 family of operating systems available from Microsoft Corporation. The
19 functionality described below is implemented using standard programming
20 techniques, including the use of OLE and COM interfaces such as described in
21 Brockschmidt, Kraig; *Inside OLE 2*; Microsoft Press, 1994, which is hereby
22 incorporated by reference.

23 More recent Windows operating systems utilize what is referred to as the
24 Win32 API: a well-defined set of interfaces that allow application programs to
25 utilize functionality provided by the Windows operating systems. The Win32 API

1 is documented in numerous texts, including Simon, Richard; *Windows 95 Win32*
2 *Programming API Bible*; Waite Group Press, 1996, which is hereby incorporated
3 by reference. General familiarity with this type of programming is assumed
4 throughout the following discussion.

5 Overall Functionality and Architecture

6 Fig. 2 shows architectural components of a protected storage system in
7 accordance with the invention for storing data items and for protecting them from
8 unauthorized access. The protected storage system allows application programs to
9 securely store data items that must be kept private and free from tampering. Such
10 data items might include cryptographic keys, passwords, financial information,
11 trust profiles, etc. The storage system is designed to hold small items of core
12 secret data in a central and common storage location; if a lot of data is to be
13 protected, a bootstrap secret (such as an encryption key) may be stored in the
14 storage system rather than the data itself. This enables data items to be moved
15 when appropriate to small, secure hardware devices such as smart cards, and also
16 avoids unnecessary overhead which would otherwise be required to secure large
17 data items.

18 The protected storage system is executed by a computer such as described
19 above with reference to Fig. 1. Application programs, such as application
20 program 102 shown in Fig. 2, are also executed by the computer.

21 Storage system 100 includes a storage server component 104, also referred
22 to as a dispatcher. Generally, the storage server, through the Pstore interface 110,
23 receives data items from application programs, securely stores the data items, and
24 returns such data items in response to requests from application programs. The
25 storage server also performs authentication and verification procedures with

1 respect to the requesting application programs, as will be explained in more detail
2 below.

3 Associated with the storage server are a plurality of installable storage
4 providers 106 and a plurality of installable authentication providers 108. Specified
5 storage providers are called by the storage server to securely store and retrieve
6 data items. One or more authentication providers are called by the storage server
7 to identify and/or authenticate current computer users.

8 A default storage provider is implemented within the storage system. The
9 default storage provider encrypts data items and then stores them on a hard disk or
10 floppy disk. The encryption is based on one or more keys that are derived from
11 authentication of the current computer user. The default storage provider also
12 verifies the integrity of data items when retrieving and decrypting them.

13 A default authentication provider is also implemented within the storage
14 system. The default authentication provider is called by the storage server to
15 identify current computer users based on previously completed operating system
16 logon procedures. Specifically, the default authentication provider identifies the
17 current computer user based on the logon identification and password provided by
18 the user while logging on to the computer's operating system or to a network
19 operating system.

20 Although default storage and authentication providers are implemented,
21 additional providers can be installed in the future to take advantage of new storage
22 and authentication technologies. For example, a smart card storage provider might
23 be installed to allow storage of core data items on a smart card. A smart card
24 authentication provider might similarly be provided to authenticate users by
25

1 requiring them to insert their smart cards into a smart card reader. In either case,
2 the smart card could utilize public-key cryptographic techniques.

3 Well-defined COM interfaces are used between the storage server and the
4 various providers, allowing new providers to be easily installed and registered
5 with the storage server. Application programs are able to make the same calls to
6 storage server 102 regardless of which providers are used. Because of this,
7 application programs can be written to take advantage of future technologies by
8 simply interacting with storage server 102, and without having to concern
9 themselves with the details of such future technologies.

10 To increase security, the protected storage system is implemented in a
11 different address space than the calling application programs. Communications
12 across the process or address space boundary take place using remote procedure
13 calls (RPCs). Such calls can be made when operating under Windows operating
14 systems and other operating systems. The functionality and formatting of RPC
15 calls is documented in the Microsoft Win32 Software Development Kit.

16 Although application programs can make RPC calls directly, this
17 complexity is avoided by providing a dynamically linked library (DLL) that can be
18 executed in the application programs' address spaces. This library, referred to as
19 Pstore Interface 110 in Fig. 2, implements a plurality of interfaces and associated
20 methods that can be called by the application programs to exploit the full
21 functionality of the protected storage system. The interfaces include methods for
22 creating and reading data items, as well as other useful functions as described in
23 an appendix to this document. The interfaces and methods in the described
24 embodiment are implemented using the COM (component object model)
25 interfaces of the Windows operating system.

Protected-Data Access Control

The protected storage system described herein has powerful data access control capability. The storage system offers two levels of data protection: application-level protection and user-level protection. At the application level, the storage server returns requested data items only to authorized requesting application programs. Furthermore, the storage server authenticates requesting application programs before returning individual data items. Application program authentication refers to a process of determining whether an application program has been tampered with, or to an alternative process of verifying a program's trustworthiness through use of public/private key cryptographic digital signatures or other means. Microsoft Authenticode is an available mechanism for verifying, through the use of digital signatures, that an application program has been published by a specified person, group, or organization, and that it is therefore trustworthy. Authenticode functionality is publicly available from Microsoft Corporation as part of its Win32 Software Development Kit.

In the embodiment describe herein, data items are organized in a hierarchical fashion by specifying types and subtypes as follows:

Type—Subtype—Data Item

There are predefined types and subtypes, and application programs can create new types and subtypes. Different protection levels can be established for data items falling under certain types and subtypes. Specifically, an *access rule set* is specified for each subtype. An access rule set contains rules for different types or subtypes of data items. Access to a data item of a particular subtype is granted if any single rule of the corresponding rule set is satisfied. Each access rule comprises a mode and one or more access clauses; all of the access clauses must

1 be satisfied before the rule is considered satisfied. The mode indicates the type of
2 access allowed if all the clauses in a rule are satisfied. Currently, there are two
3 access modes defined: *read* and *write* access.

4 There are currently three types of access clauses: *Authenticode*, *Binary*
5 *Check*, and *Security Descriptor*. *Authenticode* verifies the application program
6 requesting access to the protected data is trusted and can optionally determine
7 whether the originator, and thus the originator's application, can be trusted.
8 *Binary Check* ensures that a program has not been tampered with since
9 installation. The *Security Descriptor* clause provides access based on Windows
10 NT access control lists (ACLs).

11 *Authenticode* is a well-documented product and service available from
12 Microsoft Corporation. If the *Authenticode* clause was specified at the time of
13 subtype creation, a check is made to see if the requesting application was signed or
14 not, and if signed, by whom. The clause may specify a particular root, certificate
15 issuer, publisher (signer), program name, or some combination of the foregoing.
16 Access will not be granted unless the specified criteria are met. If no criteria
17 specified, the verification amounts to allowing any *Authenticode*-verified
18 application or module access to the data. *Authenticode* checking also verifies the
19 binary image of the module under inspection.

20 The *Binary Check* is implemented by taking a hash of a binary image of an
21 application program at initialization. When the application program asks for data
22 at a later time, the storage system again takes a hash of the memory image and
23 compares it to the original hash. The two hashes must match before the protected
24 storage system will allow the application program to access requested data. Thus,
25 if the application has changed since it was installed, and therefore is likely to have

1 been tampered with, the data will be protected and access to the data by the
2 application will be denied.

3 The Security Descriptor clause is intended to allow access only to specified
4 users or groups, and is enforced on Windows NT platforms. This clause gets the
5 necessary information about the users and groups from the ACLs contained in the
6 Windows NT security descriptor.

7 At the user level, the storage server allows access to individual data items
8 depending on the current computer user; by default, only the user responsible for
9 creating the data item is allowed to access it. However, a user can override this
10 default behavior by specifying appropriate options when creating and saving data
11 items, or the user can later modify access rights to the data.

12 Users and application programs can specify security styles, which specify a
13 degree and/or type of confirmation or authentication is required to access a
14 particular data item; for instance, whether a password is required. The current
15 embodiment, with the default authentication provider, supports the following
16 access styles:

- 17 • Silent access: no user interaction required. Authentication is based on a
18 previously completed computer or network operating system
19 authentication procedure. In most cases, this type of authentication
20 relies on the user being able to enter the correct password during a
21 previous logon procedure, and no further interaction is required when
22 protected data is actually accessed.
 - 23 • Logon password: a dialog box is presented requiring the user to enter
24 the password previously used to logon to the computer or network.
- 25

- User-defined password: the user specifies a password when an item is initially stored, and must enter the password before the data can be accessed again. Such passwords can be different for different data items, or groups of data items can be stored under the same password.
- OK/cancel: when an application attempts to access the data, a dialog box appears. The user responds to the dialog box by clicking on an OK or deny button, thereby granting/denying access to the data by a requesting application program.

As is apparent from the different types of access styles, accessing items in protected storage may require user interaction. This interaction is implemented through the use of a user alert dialog box. Typically, the user will be required to enter a password in response to a user alert dialog box. However, different authentication providers might require different types of responses (such as physical insertion of a hardware token or biometric authentication procedures).

To prevent attacking programs from presenting similar user alert dialogs, and thereby gaining access to secret data, the user alert dialogs can be customized by the user. Specifically, a user can specify a particular background or digital watermark to be used in the user alert dialog box. Alternatively, such a watermark can be randomly generated for the user. The user will become familiar with whatever watermark has been selected, and will thus recognize unauthorized dialog boxes generated by attacking applications.

Data Encryption, Decryption, and Authentication

Different storage providers may protect stored data in different ways. However, some type of cryptography will usually be employed. The default storage provider described herein uses a password-based encryption scheme,

1 wherein data items are encrypted based on a user-supplied password, or some
2 other code related to user authentication, before storing the data items. When
3 retrieving the data items, decryption is based on the same password or code.

4 When a data item is protected by the "user-defined password" security style
5 mentioned above, the user explicitly enters a password for each data item during
6 an authentication step that is invoked prior to allowing access to an individual data
7 item. In the case of "silent access," however, encryption and decryption are based
8 on a password or other code that is supplied by the current computer user during a
9 previous computer or network operating system authentication or logon procedure.
10 Typically, a user's logon name and password are used to form or derive a key that
11 is used for encrypting and decrypting data items.

12 In the described embodiment, a multi-level key technique is used to encrypt
13 data items based on user-supplied codes or passwords. This technique is
14 illustrated in Fig. 3. In this implementation, encryption and decryption use one or
15 more keys that are derived from the supplied passwords or logon codes. As
16 mentioned, the password or code can either be gathered from a previous
17 authentication step, or the storage system might prompt the current computer user
18 for a password.

19 Generally, an item key is randomly generated for each data item. The data
20 item is encrypted with its corresponding item key. An item authentication key is
21 also generated randomly for each item and is used to generate an item
22 authentication code. Item authentication codes are used during decryption to
23 verify that data items are decrypted correctly.

24 The item key and item authentication key are then encrypted using a master
25 key. The master key is a randomly generated number. A master authentication

1 key is also generated and used to calculate a key authentication code so that the
2 correct decryption of the item key and item authentication key can be verified
3 later. Finally, the master key and master authentication key are encrypted using a
4 password that is derived from user authentication or identification.

5 With reference now to the specific steps of Fig. 3, an individual data item
6 that is to be encrypted and stored is referenced by numeral 130. A step or
7 operation 131 is performed of encrypting data item 130 using an item key 132.
8 Specifically, cryptographic key 132 is used to perform a DES encryption on data
9 item 130. Item key 132 is generated as a random number by the default storage
10 provider.

11 The storage provider also performs a step 133 of generating an item
12 authentication code for individual data item 130. The item authentication code is
13 generated using a MAC (message authentication code) in conjunction with a
14 randomly generated item authentication key 134. MACs are described in the
15 Schneier text mentioned above.

16 A further step 140 is performed of encrypting the item key 132 and the item
17 authentication key 134 with a master key 141, again using the DES encryption
18 mentioned above. The master key is a random number. A step 142 comprises
19 generating a key authentication code for the combination of the item key and the
20 item authentication key. The key authentication code is generated with a MAC in
21 conjunction with a randomly generated master authentication key 143.

22 A step 145 is performed of encrypting the master key and the master
23 authentication key with a user key 146. This is again a DES encryption.

24 The user key is derived from the user-supplied password or code,
25 referenced in Fig. 3 by numeral 147. To generate the user key, the user-supplied

1 password 147 is appended to a random number referred to as a salt 148, and
2 hashed in a step 149 using an SHA-1 hashing function. This results in a number
3 that is used as the user key.

4 Once these steps are performed, the storage server stores the encrypted
5 individual data item, the item authentication code, the encrypted item key, the
6 encrypted item authentication key, the key authentication code, the encrypted
7 master key, and the encrypted master authentication key, to be retrieved later when
8 requested by an authorized application program.

9 Retrieval comprises the reverse process. The encrypted items are retrieved
10 from storage. The storage provider derives the user key from the user-supplied
11 password and uses the user key to decrypt the master key and master
12 authentication key. The master authentication key is used in conjunction with the
13 specified MAC to verify that the master key decrypted correctly. The master key
14 is then used to decrypt an appropriate item key and corresponding item
15 authentication key. The item authentication key is used in conjunction with the
16 MAC to verify that the item key decrypted correctly. The item key is then used to
17 decrypt the actual data item.

18 This process allows all of a user's data items to be controlled by a single
19 master key that is in turn encrypted as a function of the user's password. The
20 advantage of this scheme is that data items do not have to be re-encrypted when
21 the user changes his or her password. Rather, only the master key needs to be
22 encrypted again.

23 Verification of Storage System Integrity

24 The storage server, the storage providers, and the authentication providers
25 employ a security interlock mechanism to prevent security violations that might

1 result from tampering with system components. This mechanism utilizes
2 cryptographic techniques.

3 One motivation for the security interlock mechanism is to prevent non-
4 authorized providers from being loaded by the storage server. It is particularly
5 important to prevent a non-authorized module from masquerading as an authorized
6 provider, since such a non-authorized module could steal secret data from the
7 system. Another motivation is to prevent tampering with the storage server itself.

8 When the server and providers are shipped, they are digitally signed with
9 the private key of a public/private cryptographic key pair—the private key has a
10 corresponding public key. The public key is then hard-coded into the various
11 modules of the server and providers. The server and the providers are configured
12 to verify each others' signatures using the public cryptographic key whenever an
13 individual component is loaded and executed. When the server is loaded, it first
14 checks its own integrity by checking its own digital signature with the public key.
15 The server then checks the digital signatures of other core components as they are
16 loaded. As each component is loaded, it checks the digital signature of the server.
17 If any integrity check fails, none of the components will operate.

18 Authentication of Requesting Application Programs

19 As discussed above, access to data items can be restricted based on which
20 application programs are trying to access the data items. For this feature to be
21 reliable, the storage system needs to verify that application programs are who they
22 say they are, and that they have not been tampered with. This process is referred
23 to as program authentication. One option is to authenticate programs based on a
24 binary check. Such an authentication is performed by two storage server modules:
25 the *identification module* and the *enforcement module*.

1 The identification module is responsible for interrogating the client that is
2 calling the storage server. In order to identify a process associated with a request,
3 the following steps occur:

- 4 1. The client application program identifies itself to the server, presenting
5 two pieces of information: a process ID, and a thread handle. The
6 process ID is obtained using the GetCurrentProcessId() system call; the
7 thread handle is obtained using the GetCurrentThread() and
8 DuplicateHandle() system calls.
- 9 2. The storage server opens a handle to the client, using the process ID in a
10 call to the system call OpenProcess(). The storage server saves this
11 handle for later use.
- 12 3. The client makes access requests for data items.
- 13 4. The server uses the process handle obtained above to analyze the
14 memory address space associated with the client process. The server
15 also uses this handle to query the underlying operating system about
16 what executable modules (.exe, .dll, etc. files) are present in the
17 associated process, in addition to determining module load addresses;
18 the exact method used to query the operating system varies depending
19 on the operating system.
- 20 5. The server now has a complete list of modules associated with the
21 client, and uses it to analyze the call stack associated with the thread
22 handle obtained above. The StackWalk() system call is utilized to
23 determine the chain of callers associated with the client.

24 The enforcement module uses results provided by the identification module
25 in performing the following checks:

1. Verifying that the image loaded into the client process has not been tampered with on-disk. This is accomplished by storing a cryptographic representation of the file(s) that are to be granted access. This cryptographic representation is stored alongside the data. There can be two cryptographic representations of the file:
 - The entire file is read and then subjected to the SHA-1 cryptographic hash. The output of the hash is stored alongside the data. When subsequent access to the data is requested, the hash is recomputed against the on-disk file, and then compared to that stored alongside the data. If these compare correctly, the process continues to check 2, below.
 - The file is subject to public key certificate-based validation. This uses Microsoft Authenticode calls to verify that the image has not been tampered with. Authenticode handles hashing the disk image internally. This cryptographic representation of the file is more flexible, because it also supports validation against various fields in the certificate attached to the specified file. After the Authenticode verification takes place, the system analyzes the certificate contents, to make sure they match those that were stored alongside the data being accessed.
2. Verifying that the image on disk matches that loaded into the client process.
 - The module to be checked is “mapped” into the server address space, using the `CreateFileMapping()` and `MapViewOfFile()` system API calls.

- Relocation fixups are applied to the mapped image if necessary—only if the image did not load at the preferred address in the client address space.
- The system loops over the image header, looking for read-only sections such as code sections, resources, and read-only data. For each section, it updates an SHA-1-based cryptographic hash.
- The process handle output from the identification module is now used to read the memory address space where the module is loaded. This is accomplished by using the ReadProcessMemory() system call. Each section of memory is read in the manner outlined in the previous step, updating a cryptographic hash as the process proceeds.
- The system compares the two hashes resulting from the immediately preceding steps. If they match, the image in memory has not been tampered with.

Application Interface Functions

As described above, interfaces are exposed to application programs so that application programs can take advantage of protected storage features without having to implement sophisticated encryption schemes and without having to make RPC calls. These interfaces and their functions are described in an attached appendix that forms part of this document. The appendix also provides explanations regarding the proper usage of the interfaces.

Conclusion

The invention provides a versatile and efficient architecture that provides a number of advantages over the prior art. One significant advantage is that

1 different application programs can utilize a single, provided server to store core
2 data secrets in a central storage area. This promotes consistency among the
3 applications and removes significant overhead from the applications. The user
4 interface is one area that benefits from the consistency provided by the storage
5 system described above, since user prompts are generated by the system rather
6 than by the individual application programs. Storing data items in a uniform
7 manner also allows them to be managed by a single management program that is
8 independent of the application programs themselves.

9 Another significant advantage of the invention is that the underlying details
10 of securing data items are hidden from calling application programs. Thus,
11 program developers do not have to implement sophisticated security measures;
12 such measures can be implemented with simple calls to the storage system
13 described herein. An added benefit is that new technologies such as smart cards
14 will be available to application programs without extensive reprogramming.

15 The invention protects secrets from user-oriented and software-oriented
16 attacks, including attacks from viruses. Significantly, access control is managed
17 outside the application programs that generate and access data items. Because
18 applications do not have direct access to keying material or other control data,
19 access to one piece of data does not imply access to any other data. Furthermore,
20 the storage system itself does not retain the information required to decrypt stored
21 data items. Rather, the user must be present and must supply a correct password to
22 allow data decryption.

23 A further important benefit of the invention is that users are not forced to
24 explicitly enter passwords when data access is required. Rather, user
25 authentication is performed once, when the user logs on to the computer or

1 network. This logon information is used for both user authentication and to derive
2 keys for data encryption and decryption.

3 Although the invention has been described in language specific to structural
4 features and/or methodological steps, it is to be understood that the invention
5 defined in the appended claims is not necessarily limited to the specific features or
6 steps described. Rather, the specific features and steps are disclosed as exemplary
7 forms of implementing the claimed invention.

1 CLAIMS

2 1. A system for storing data items and for protecting them from
3 unauthorized access, comprising:

4 a storage server that receives data items from application programs and that
5 returns such data items in response to requests from application programs;

6 one or more storage providers that are called by the storage server and that
7 securely store and retrieve the data items;

8 one or more authentication providers that are called by the storage server to
9 identify current computer users.

10
11 2. A system as recited in claim 1, wherein the storage server is
12 configured to call installable storage providers.

13
14 3. A system as recited in claim 1, wherein the storage server is
15 configured to call installable authentication providers.

16
17 4. A system as recited in claim 1, wherein the storage server executes in
18 a different address space than the application programs.

19
20 5. A system as recited in claim 1, wherein the storage server executes in
21 a different address space than the application programs and is called via remote
22 procedure calls.

23

24

25

1 6. A system as recited in claim 1, wherein said one or more
2 authentication providers include an authentication provider that identifies users
3 based on a previous network authentication.

4
5 7. A system as recited in claim 1, wherein said one or more storage
6 providers include a storage provider that encrypts data items before storing them
7 and decrypts data items before retrieving them.

8
9 8. A system as recited in claim 1, wherein said one or more storage
10 providers include a storage provider that verifies the integrity of data items when
11 retrieving them.

12
13 9. A system as recited in claim 1, wherein said one or more storage
14 providers include a storage provider that encrypts and decrypts data items using
15 one or more keys that are derived from authentication of the current computer
16 user.

17
18 10. A system as recited in claim 1, wherein said one or more storage
19 providers include a storage provider that encrypts and decrypts data items using
20 one or more keys that are derived from a user-supplied code, and wherein the
21 storage server prompts the current computer user for the user-supplied code.

22
23
24
25

1 11. A system as recited in claim 1, wherein said one or more storage
2 providers include a storage provider that encrypts and decrypts data items using
3 one or more keys that are derived from a network logon code supplied by the
4 current computer user.

5
6 12. A system as recited in claim 1, wherein said one or more storage
7 providers include a storage provider that securely stores and retrieves data items
8 using one or more keys that are derived from a user-supplied code.

9
10 13. A system as recited in claim 1, wherein said one or more storage
11 providers include a storage provider that securely stores and retrieves data items
12 using one or more keys that are derived from a network logon code supplied by
13 the current computer user.

14
15 14. A system as recited in claim 1, wherein said one or more storage
16 providers include a storage provider that stores data items in accordance with the
17 following steps:

18 encrypting individual data items with item keys;

19 encrypting the item keys with a master key;

20 encrypting the master key with a user key that is derived from a user-
21 supplied code;

22 storing the encrypted individual data items, the encrypted item keys, and
23 the encrypted master key.

24
25

1 15. A system as recited in claim 1, wherein said one or more storage
2 providers include a storage provider that stores data items in accordance with the
3 following steps:

4 encrypting individual data items with item keys;

5 generating item authentication codes for individual data items using item
6 authentication keys;

7 encrypting the item keys and the item authentication keys with a master
8 key;

9 generating key authentication codes for item keys and item authentication
10 keys using a master authentication key;

11 encrypting the master key and the master authentication key with a user key
12 that is derived from a user-supplied code;

13 storing the encrypted individual data items, the item authentication codes,
14 the encrypted item keys, the encrypted item authentication keys, the key
15 authentication codes, the encrypted master key, and the encrypted master
16 authentication key.

17
18 16. A system as recited in claim 1, wherein said one or more storage
19 providers include a storage provider that retrieves data items in accordance with
20 the following steps:

21 retrieving encrypted individual data items, encrypted item keys
22 corresponding to the encrypted individual data items, and an encrypted master
23 key;

24 decrypting the encrypted master key with a user key that is derived from a
25 user-supplied code:

1 decrypting the encrypted item keys with the decrypted master key;
2 decrypting the encrypted individual data items with the corresponding
3 decrypted item keys.

4
5 17. A system as recited in claim 1, wherein the storage server allows
6 access to individual data items depending on the current computer user.

7
8 18. A system as recited in claim 1, wherein the storage server returns
9 requested data items only to authorized requesting application programs.

10
11 19. A system as recited in claim 1, wherein the storage server returns
12 requested data items only to authorized requesting application programs, and
13 wherein the storage server authenticates requesting application programs before
14 returning individual data items.

15
16 20. A system as recited in claim 1, wherein the storage server returns
17 requested data items only to authorized requesting application programs, and
18 wherein the storage server authenticates the requesting application program using
19 public key cryptography before returning individual data items.

20
21 21. A system as recited in claim 1, wherein the storage server is
22 responsive to application program requests to present user dialogs allowing the
23 current computer user to specify passwords to be used by the storage provider to
24 securely store and retrieve data items.

25

22. A system as recited in claim 1, wherein the storage server, the storage providers, and the authentication providers are individually signed by a private cryptographic key that corresponds to a public cryptographic key; the storage server, the storage providers, and the authentication providers being configured to verify each others' signatures using the public cryptographic key.

23. A system for storing data items and for protecting them from unauthorized access, comprising:

a storage server that receives data items from application programs and that returns such data items in response to requests from application programs, wherein the storage server executes in a different address space than the application programs and is called via remote procedure calls;

a storage provider that is called by the storage server to securely store and retrieve the data items, wherein the storage provider encrypts data items before storing them using one or more keys that are derived from authentication of the current computer user, the storage provider verifying the integrity of data items when retrieving them;

an authentication provider that is called by the storage server to identify current computer users, wherein the authentication provider identifies users based on a previous operating system logon procedure.

20

24. A system as recited in claim 23, wherein said one or more keys are derived from an operating system logon code supplied by the current computer user.

25. A system as recited in claim 23, wherein said one or more keys are derived from a user-supplied code.

25

26. A system as recited in claim 23, wherein the storage provider stores data items in accordance with the following steps:

encrypting individual data items with item keys;

30

encrypting the item keys with a master key;

encrypting the master key with a user key that is derived from a user-supplied code;

storing the encrypted individual data items, the encrypted item keys, and the encrypted master key.

5

27. A system as recited in claim 23, wherein the storage provider stores data items in accordance with the following steps:

encrypting individual data items with item keys;

generating item authentication codes for individual data items using item authentication keys;

10

encrypting the item keys and the item authentication keys with a master key;

generating key authentication codes for item keys and item authentication keys using a master authentication key;

15

encrypting the master key and the master authentication key with a user key that is derived from a user-supplied code;

storing the encrypted individual data items, the item authentication codes, the encrypted item keys, the encrypted item authentication keys, the key authentication codes, the encrypted master key, and the encrypted master authentication key.

20

28. A system as recited in claim 23, wherein the storage provider retrieves data items in accordance with the following steps:

retrieving encrypted individual data items, encrypted item keys corresponding to the encrypted individual data items, and an encrypted master key;

25

decrypting the encrypted master key with a user key that is derived from a user-supplied code;

decrypting the encrypted item keys with the decrypted master key;

decrypting the encrypted individual data items with the corresponding decrypted item keys.

30

29. A system as recited in claim 23, wherein the storage server returns requested data items only to authorized requesting application programs.

30. A system as recited in claim 23, wherein the storage server returns requested data items only to authorized requesting application programs, and wherein the storage server authenticates requesting application programs before returning individual data items.

5

31. A system as recited in claim 23, wherein the storage server returns requested data items only to authorized requesting application programs, and wherein the storage server authenticates requesting application programs using public key cryptography before returning individual data items.

10

32. A system as recited in claim 23, wherein the storage server is responsive to application program requests to present user dialogs allowing the current computer user to specify passwords to be used by the storage provider to securely store and retrieve data items.

15

33. A system as recited in claim 23, wherein the storage server and the storage provider are individually signed by a private cryptographic key that corresponds to a public cryptographic key; the storage server and the storage provider being configured to verify each others' signatures using the public cryptographic key.

20

34. A method of storing user and application secrets and for protecting them from unauthorized access, comprising the following steps:

authenticating a current computer user based on a previous logon authentication performed by an operating system;

25

receiving individual data items from application programs;

encrypting the data items using one or more keys that are derived from said previous logon authentication of the current computer user;

storing the encrypted data items.

30

35. A method as recited in claim 34, wherein the storing step comprises storing encrypted data items from different application programs in a common storage area.

36. A method as recited in claim 34, further comprising a step of deriving said one or more keys based on a computer logon password.

38. A method as recited in claim 34, wherein the encrypting step
5 comprises:

encrypting individual data items with item keys;

encrypting the item keys with a master key;

encrypting the master key with a user key that is derived from said previous authentication of the current computer user;

10 the method further including a step of storing the encrypted item keys and the encrypted master key.

38. A method as recited in claim 34, further comprising the following additional steps:

15 retrieving encrypted individual data items, encrypted item keys corresponding to the encrypted individual data items, and an encrypted master key;

decrypting the encrypted master key with a user key that is derived from said previous authentication of the current computer user;

decrypting the encrypted item keys with the decrypted master key;

20 decrypting the encrypted individual data items with the corresponding decrypted item keys.

39. A method as recited in claim 34, comprising a further step of allowing access to individual data items depending on the current computer user.

25 40. A method as recited in claim 34, comprising a further step of returning requested data items only to authorized requesting application programs.

41. A method as recited in claim 34, comprising the following additional steps:

returning requested data items only to authorized requesting application programs;
authenticating requesting application programs before returning individual data
5 items.

42. A method as recited in claim 34, comprising a further step of presenting
user dialogs in response to application program requests for data items, the user dialogs
allowing the current computer user to specify passwords to be used by the storage provider
10 to decrypt data items.

43. A method of storing user and application secrets and for protecting them
from unauthorized access, comprising the following steps:

receiving individual data items from application programs; encrypting the
15 individual data items with item keys; encrypting the item keys with a master key;
encrypting the master key with a user key;

storing the encrypted data items, the encrypted item keys, and the encrypted master
key.

44. A method as recited in claim 43, further comprising the following
20 additional steps:

generating item authentication codes for individual data items using item
authentication keys;

encrypting the item authentication keys with the master key;

25 generating key authentication codes for item keys and item authentication keys
using the master authentication key;

encrypting the master authentication key with the user key;

storing the item authentication codes, the encrypted item keys, the encrypted item
authentication keys, the key authentication codes, and the encrypted master authentication
30 key.

45. A method as recited in claim 43, further comprising the following additional steps:

retrieving encrypted individual data items, the encrypted item keys corresponding to the retrieved encrypted individual data items, and the encrypted master key;

5 decrypting the encrypted master key with the user key;

decrypting the encrypted item keys with the decrypted master key;

decrypting the encrypted individual data items with the corresponding decrypted item keys.

10 46. A method as recited in claim 43, further comprising a step of deriving the user key from a user authentication step.

47. A method as recited in claim 43, further comprising a step of deriving the user key from a computer logon code.

15

48. A method as recited in claim 43, further comprising a step of deriving the user key from a previous authentication of the current computer user.

20 49. A method as recited in claim 43, further comprising a step of deriving the user key from network authentication of the current computer user.

50. A method of storing user and application secrets and for protecting them from unauthorized access, comprising the following steps:

receiving individual data items from application programs;

25 encrypting the data items using one or more keys that are derived from one or more user-supplied passwords;

storing the encrypted data items;

retrieving and decrypting the stored encrypted data items in response to requests from application programs.

30

51. A method as recited in claim 50, comprising a further step of presenting user dialogs in response to application program requests for data items, the user dialogs allowing the current computer user to specify the user-supplied passwords.

5 52. A method as recited in claim 34, comprising the following additional step:
allowing a user to specify a type of user authentication that will be performed before performing the retrieving and decrypting steps.

53. A method as recited in claim 50, further comprising a step of obtaining a
10 default user-supplied password during a computer logon procedure.

54. A method as recited in claim 50, further comprising a step of obtaining a default user-supplied password during a computer logon procedure, the default user-supplied password comprising a computer logon password.

15 55. A method as recited in claim 50, comprising the following additional steps:
obtaining a default user-supplied password during a network logon procedure;
obtaining additional user-supplied passwords by presenting user dialogs that allow the current computer user to specify such additional user-supplied passwords.

20 56. A method as recited in claim 50, comprising a further step of presenting user dialogs in response to application program requests for data items, the user dialogs allowing the current computer user to specify passwords to be used by the storage provider to decrypt data items.

25 57. A method as recited in claim 50, comprising a further step of allowing access to individual data items depending on the current computer user.

58. A method as recited in claim 50, comprising a further step of returning
30 requested data items only to authorized requesting application programs.

59. A method as recited in claim 50, the encrypting step comprising encrypting the individual data items with item keys, comprising the following additional steps:

receiving individual data items from application programs;

encrypting the item keys with a master key;

5 encrypting the master key with a user key that is derived from said one or more user-supplied passwords.

60. A method of storing user and application secrets and for protecting them from unauthorized access, comprising the following steps:

10 receiving individual data items from application programs;

encrypting the data items using one or more keys that are derived from one or more user-supplied passwords;

storing the encrypted data items;

15 retrieving and decrypting the stored encrypted data items in response to requests from application programs;

allowing access to individual data items depending on the current computer user;

returning requested data items only to authorized requesting application programs.

61. A method as recited in claim 60, wherein an application program performs
20 a step of specifying application programs that are authorized to access respective data items.

62. A method as recited in claim 60, wherein an application program performs
a step of specifying computer users that are authorized to access respective data items.

25

63. A method as recited in claim 60, further comprising a step of authenticating authorized requesting application programs using public key cryptography before returning individual data items.

30 64. A method as recited in claim 60, wherein the storing step comprises storing encrypted data items from different application programs in a common storage area.

65. A method of storing user and application secrets and for protecting them from unauthorized access, comprising the following steps:

receiving individual data items from different application programs;
encrypting the data items;

5 storing the encrypted data items from the different application programs in a common storage area.

66. A method as recited in claim 65, comprising a further step of allowing access to individual data items depending on the current computer user.

10

67. A method as recited in claim 65, comprising a further step of returning requested data items only to authorized requesting application programs.

68. A method as recited in claim 65, comprising the following additional
15 steps:
returning requested data items only to authorized requesting application programs;
authenticating requesting application programs before returning individual data items.

20

69. A method as recited in claim 65, comprising a further step of presenting user dialogs in response to application program requests for data items, the user dialogs allowing the current computer user to specify passwords to be used by the storage provider to decrypt data items.

25

70. A method as recited in claim 65, wherein the encrypting step is based on one or more keys that are derived from authentication of the current computer user.

71. A method as recited in claim 65, wherein the encrypting step is based on one or more keys that are derived from a user-supplied code.

30

72. A method as recited in claim 65, wherein the encrypting step is based on one or more keys that are derived from a computer logon code supplied by the current computer user.
